A 3D Laser Scanning Study on Slab-on-Grade

How Bruce mentors and guides young professionals

F-numbers and Textured Concrete Surface Finishes

Parking structures and parking lots with swirl and broom finishes

by Lingfeng (Leo) Zhang

Slab-on-Ground Thickness Measurement

A comparison of data collected using laser scanning, ground-penetrating radar, impact-echo, and coring methods

by Lingfeng (Leo) Zhang, James Kling

Textured finishes are surfaces of parking pavements, and wall sometimes specified for parking structures (ACI 362.1R¹), finish (Fig. 1(b)) is common other exterior concrete and ACI Committees 330, Con and 302, Construction of Concrete Structures (ACI 302.1R¹), and others (contractors are encountering specify unachievable F-numbers for swirl and broom finishes various finishing techniques these finishes. Therefore, industry's confusion regarding textured swirl and broom finishes

In a previous article,¹ we questioned the specifying F-number criteria for slabs textured finishes. In addition to industry arguments were supported by flatness measurements for a 6 in. thick, 20 x 80 ft slab-on-ground constructed by The Conco Companies, the American Society of Concrete Contractors also used the test panel to collect thickness scanning, ground-penetrating radar (GPR) and coring methods. The results are presented

Project Specification F-numbers

Some concrete contract specifications requiring finish (SOVs) as high as 50, with 35, for surfaces also specify project specification requiring specified to have a swirl finish values is not clear.

Finishing

Required or recommended textured finishes vary from whether to machine floor. This issue should be addressed and non-air-entrained concrete

Ground Truthing

Prior to the placement of reinforcing steel used a laser scanner to survey the surface compacted aggregate base in the test panel concrete placement and finishing, the same laser scanner to survey the finished panel. Point cloud database software was difference between the two surveyed surfaces thus concrete slab thickness at specific test panel point.

Thickness values were then found by in the elevations over a 1 ft horizontal grid in about 1700 thickness values, the point have easily been "mined" to obtain 17,000

But how good was this data? We could the literature that compared laser scan thickness measurements taken using other methods realized that this test panel provided a great make such comparisons, particularly because owned a GPR device and the ASCC Educa had recently purchased an IE device for use on their research projects.

We used both devices to collect thickness obtained funding from the ASCC Educational evaluate 30 cores to compare with the thickness

Presenting Laser Scan Results for Slabs-on-Ground

Deliverables tailored to the user's perspective

by Lingfeng (Leo) Zhang, James Kling, and Bruce A. Suprenant

Joint ACI-ASCC Committee 117, Tolerances, is working on the "Guide to Using Laser Scanning for Concrete Tolerances." Drafts of six chapters were presented and discussed at the second ASCC Workshop on Laser Scanning in Las Vegas, NV, USA, in January 2018. While the six chapters covered the initial part of the document, Chapters 7 and 8 on reporting laser scanning results and deliverables were not addressed. In December 2021, the American Society of Concrete Contractors (ASCC) initiated a study focused on laser scanning results and deliverables for slabs-on-ground. This article presents the recommendations from that study.

Workshops and Studies

ASCC sponsored two laser scanning workshops (January 22, 2018, and January 21, 2019), both in Las Vegas in conjunction with the World of Concrete. More than 30 attendees representing contractors, engineers, laser manufacturers, laser consultants, and laser surveyors participated in each workshop. The first workshop focused on collecting and processing laser data and the application of laser scanning to tolerance compliance. The second workshop presented laser scan results from an ASCC-sponsored study and drafts of six chapters for the new ACI-ASCC 117 guide. ASCC paid for the development of the drafts of the six chapters that have since been turned over to Joint ACI-ASCC Subcommittee 117-L, Laser Scanning.

The first ASCC study was at a construction site in Walnut Creek, CA, USA, on October 6-7, 2018. In the first part of the study, eight teams (each comprising one to three individuals) scanned portions of the project, and their measurements were compared against independently obtained reference data. The second part of the study focused on the use of laser scanning technology to determine F-numbers. The study resulted in two *Concrete International* articles.²

The second ASCC workshop focused on presenting laser scanning results to be easily understood, readily interpreted, and construction friendly. And while there was preliminary discussion about reporting laser scan data and deliverables, nothing was prepared as recommended practice. ASCC

therefore decided to initiate a second study in December 2021 in cooperation with Leo Zhang of The Conco Companies, using a 1600 ft² (150 m²) slab-on-ground test panel constructed as a mockup for broom and swirl finishes.³

Issues with Laser Scan Results

ASCC received examples of laser scan results from its contractor members. Three examples illustrate issues with the current deliverables.

Example 1: Reporting measurement precision

A general contractor hired a consultant to use a laser to provide measurements of riser heights and tread depths for a set of concrete stairs. Figure 1 shows measurements reported to the nearest 1/64 in. (0.4 mm). Precision is the level of detail of a measurement, determined by the smallest unit or fraction

Fig. 1: Laser scanning stair measurements were reported to 1/64 in. (0.4 mm). This "implied" precision is not appropriate. At the best, measurements from laser scanning should be reported at no less than 1/8 in. (3 mm) and, depending on the application, to the nearest 1/4 in. (6 mm) (Note: 1 ft = 0.3 m; 1 in. = 25 mm)

Leo

A starting point for your questions. Most organizations in the US, follow the American National Standards Institute (ANSI) for Standards.

If you follow their procedures and can prove it, then you can become an ANSI approved Standards Development Organization (SDO).

The SDO process is complicated and expensive. ACI and ASTM are SDO's, ASCC is not. Learn all you want to here: <https://www.ansi.org/american-national-standards/info-for-standards-developers/accreditation>

Some ACI stuff is shown below.

ASTM is an SDO, however, you can have an ASTM standard without a precision and bias statement. There are some ASTM standards that will never have a precision and bias statement.

I was told by an ASTM E1155 member that they approved the inclusion of laser scanning based on Phillip Lorezon's one example. They said they didn't know how to keep it out. I am not sure why they took this approach, but I was told they did. E1155 has a precision and bias statement that is only for the Dipstick.

ASTM has a standard for preparing precision and bias statement. Shown below and attached. Also attached is the ASTM for "Conducting an Interlaboratory Study to Determine the Precision of a Test Method."

ASTM requires a minimum number of 6 labs, testing two materials (items), at least twice. This should sound familiar. We had 6 laser scanners, testing two floors (the slab on grade and elevated), twice (Saturday and Sunday). This we set up the testing in CA to qualify to make a precision statement about laser scanning. We did this for the vertical and horizontal accuracy (shooting at targets) and then for F-numbers.

The issue with F-numbers is that it appears that the precision varies with the FF. So, we only got one precision for an FF of about 25 in CA. It needs to be done, like the Dipstick, for FF ranges, like 20-25, 25 to 30, 30 to 35, 35 to 40, and so on.

It's unfortunate that the laser industry will not set up and do the work. I don't think they want anyone to know the precision, however, now that more laser scanning is being used in court. I have seen articles stating those issues.

See attached article on "Accuracy and Repeatability of the Laser Scanner and Total Station for Crime and Accident Scene Documentation."

A 3D Laser Scanning Study on Slab-on-Grade

How Bruce mentors and guides young professionals

INFORMATION

1. Pad was scanned on the pour day following grading activities;
2. Deviation map was created by comparing bottom of rat slab model and pad scan;
3. Overbreak volume was calculated by comparing bottom of rat slab model and pad scan with a credit of 0.1' layer of volume;
4. Deviation measurements were provided at the worst spots as shown on this exhibit with unit in "feet";
5. Pad was scanned with Leica P40 laser scanner and survey controls were transferred from prisms provided by BKF;
6. "IN" on the legend represents encroachment, and "OUT" represents the opposite way.

DATA ANALYSIS

1. Approximately 63% of the pad areas were within +/- 0.1' tolerance;
2. Overbreak volume = 66.60 cy.
