First printing, February 2020

Discussion is welcomed for all materials published in this issue and will appear ten months from this journal's date if the discussion is received within four months of the paper's print publication. Discussion of material received after specified dates will be considered individually for publication or private response. ACI Standards published in ACI Journals for public comment have discussion due dates printed with the Standard.

The Institute is not responsible for the statements or opinions expressed in its publications. Institute publications are not able to, nor intended to, supplant individual training, responsibility, or judgment of the user, or the supplier, of the information presented.

The papers in this volume have been reviewed under Institute publication procedures by individuals expert in the subject areas of the papers.

PREFACE

Offshore and marine concrete structures have not received enough attention in the recent past, at least in the United States. The complexity and safety concerns associated with these structures are such that they probably need more attention compared to many other types of concrete structures. Also, offshore and marine concrete structures are so global in nature that there is a higher need for better coordination and synchronization of design, construction, inspection, and maintenance practices in different parts of the world.

A two-part session, titled “Offshore and Marine Concrete Structures: Past, Present, and Future,” was held at the Spring 2019 ACI Concrete Convention and Exposition on March 24-28 in Quebec City, Quebec, Canada. The session, sponsored by ACI Committee 357, Offshore and Marine Concrete Structures, highlighted accomplishments of the past, current state-of-the-practice, and a path for the future. This ACI Special Publication (SP) is a compilation of select papers presented at the session. The efforts of all the reviewers in assuring the quality of this publication is greatly acknowledged.

TABLE OF CONTENTS

SP-337-1:

Design and Construction Overview of Offshore Concrete Gravity-Based-Structures:
Past, Present, and Future 1-20
Authors: Widiyanto, Jameel Khalifa, Erik Åldstedt, Kåre O. Hæreid, Kjell Tore Fosså

SP-337-2:

Hebron Offshore Concrete Gravity-Based-Structure: Novel Design and
Construction Techniques 21-39
Authors: Widiyanto, Jameel Khalifa, Kåre O. Hæreid, Kjell Tore Fosså, Anton Gjørven

SP-337-3:

Barbours Cut Terminal - Container Port Wharf Expansion Design..... 40-57
Authors: Jeremiah D. Fasl and Carl J. Larosche

SP-337-4:

Testing and Inspection Techniques for Offshore and Marine Structures.....58-77
Author: Mohammad S. Khan

SP-337-5:

Concrete Mix Design Development for Offshore Structures 78-88
Authors: Kjell Tore Fosså, Widiyanto

SP-337-6:

Performance of Concrete in a Harsh Marine Environment for 25 Years..... 89-100
Authors: Edward (Ted) Moffatt, Michael Thomas and Andrew Fahim

SP-337-7:

Importance of Structural Assessment before Rehabilitation Case Study:
Waterfront Concrete Pier..... 101-116
Authors: Pericles C. Stivaros, Varoujan Hagopian, and Alan D. Pepin

SP-337-8:

LaGuardia Airport Design Build for Extending Runway Decks for
Safety Area Improvements, Queens, NY 117-135
Authors: Anthony Devito, Alex Krutovskiy and Leszek Czajkowski

Design and Construction Overview of Offshore Concrete Gravity-Based-Structures: Past, Present, and Future

Widianto, Jameel Khalifa, Erik Åldstedt, Kåre O. Hæreid, Kjell Tore Fosså

Synopsis: An offshore concrete Gravity-Based-Structure (GBS) is a massive concrete structure placed on the seafloor and held in place strictly by its own weight, without need for anchors. This paper focuses on concrete GBSs used as the base of integrated oil drilling and production platforms. The summary of key distinct structural features of several major GBSs, since the first Ekofisk GBS (installed in the North Sea, offshore Norway, in 1973) until the latest Hebron GBS (installed in the Grand Banks, Canada, in 2017), is presented. This paper also discusses several unique loads that GBSs have to resist. An overview of structural analysis and design methodology is described in detail. Key considerations for preliminary sizing of GBS structural components are presented. Typical construction phases, methods, and the importance of constructability are explained. Finally, potential future research topics that would result in a more cost-effective offshore concrete GBS are discussed.

Keywords: Floating Construction, Reinforced Concrete Design, D-regions, Structural Analysis, Offshore Structures, Strut-and-tie, Wave loads

ACI member **Widianto** is a Civil/Structural Engineer at ExxonMobil and the Chair of the Task Group 1 in ACI Committee 357, tasked to update ACI 357R-84. He was ExxonMobil Hebron GBS Concrete Design Engineer. Widianto received his BS with Highest Honors, MSE, and PhD degrees in Civil Engineering from The University of Texas at Austin, TX. He was a Lecturer for the Reinforced Concrete Design course at the University of Houston, Houston, TX, in Spring 2009. He is a member of ACI Committees 351, 357, 376, and 445-C.

ACI member **Jameel Khalifa** is ExxonMobil Engineering Manager for P'nyang Project and voting member of ACI Committee 376. He was the ExxonMobil Hebron GBS Engineering Manager. He has 35+ years of experience in project and engineering management, design, forensic engineering and construction in the oil and gas industry, including both onshore and offshore structures. He received his BS in Civil Engineering from University of Engineering and Technology, Lahore, Pakistan and his MS and PhD in Structural Engineering from University of Toronto, Toronto, Canada.

ACI Committee 357 Member **Erik Åldstedt** is Senior Civil Engineer at Multiconsult Norway AS. He is also a member of the Norwegian Concrete Association. Åldstedt has nearly 50 years of experience in structural analysis and design of industry and offshore concrete structures. He received his MS and PhD in civil engineering from the Norwegian University of Science and Technology, Trondheim, Norway.

Kåre O. Hæreid is General Manager in Concrete Structures AS. Kåre received his BSc in Civil Engineering at Bergen Ingeniør Høgskole and his MSC in Civil and Marine Engineering from NTH in Trondheim. He is registered Professional Engineer in Newfoundland & Labrador. Kåre has experience from a number of offshore concept studies and as Civil Engineering Manager for a number of major offshore concrete projects.

ACI Committee 357 Member **Kjell Tore Fosså** is Manager for Concrete Technology in Kvaerner AS and is Professor (part time) at University in Stavanger. He is chairman of committee NB25 "Guidelines for Design and Construction of Slipformed Concrete Structures (Norwegian Concrete Society). He has more than 20 years of extensive experience within construction of offshore concrete structures. Specialists in concrete material technology and slipforming of concrete structures. Received a PhD degree within slipforming of vertical concrete structures in 2001. Presently responsible for research and development programs within concrete technology and construction methods at Kvaerner.

INTRODUCTION

An offshore concrete Gravity Based Structure (GBS) is a massive concrete structure placed on the seafloor and held in place strictly by its own weight, without need for piles or anchors. This paper focuses on concrete GBSs used as the base of integrated oil drilling and production platforms (topsides). The topsides typically includes drilling, production, processing, and accommodation facilities. Table 1 provides a summary of key distinct structural features of several major GBSs, starting with the first, Ekofisk GBS (installed in the North Sea, offshore Norway, in 1973), until the latest Hebron GBS (installed in the Grand Banks, Canada, in 2017). Several major GBSs are also shown in Figure 1.

General Characteristics

In contrast to typical buildings and bridges, there are several distinct features of offshore GBSs that pose unique challenges in the structural analysis, design and construction:

- They are typically massive in size, have a complex geometry and contain a significant number of "Disturbed" or D-regions. Typical examples of D-regions are locations with abrupt changes in dimensions (change in thickness or an opening in a wall), locations where concentrated loads are applied (such as post-tensioning anchorages), or deep beams where simple beam theory does not apply.
- The structural elements are heavily loaded and highly reinforced, with average reinforcement density of over 300 kg/m³ (19 lb/ft³) compared to 75-150 kg/m³ (5-9 lb/ft³) for typical buildings and bridges. This is partly because the member thicknesses have to be limited to minimize GBS weight to allow it to float during the various construction and installation phases.
- They contain many access openings and pipe penetrations that require additional reinforcement around them to replace the reinforcement interrupted by these openings. This further increases the local reinforcement density that can be as high as 600 kg/m³ (37 lb/ft³).
- They are typically located in harsh climates leading to enormous wave loads (>1,000 MN (225,000 kip)) and sometimes ice/iceberg impact loads (>500 MN (112,000 kip)).
- Some GBSs also have a requirement to store oil, hence be leak-tight. This subjects many structural members to large differential pressures and temperatures that requires post-tensioning and other
